	Hydrology	Historical-USGS BCM	Historical-USGS BCM
Both	Simulation Period	WY 1911-2017	WY 1911-2017

Baseline Operations Model Assumptions

Eel River:

- Current minimum flow released based on 2002 Biological Opinion RPA flows
- Historical Cardno hydrology for Lake Pillsbury inflow (no climate change)
- Cardno 2018 estimates of daily unimpaired tributary accretion between E-2 and E-11
- 2017 Block Water hydrograph released from slide gate, triggered when E-11 flows drop below 250 cfs after April 1
- Maximum PVP diversion capacity = 170 cfs to best represent historical → simulated volumetric mass balance for discretionary power generation diversions (full capacity is 300 cfs; current derated capacity is 240 cfs)
- Regression equation used for the timing of Scott Dam gate closure
- Drought, Maintenance, and Testing flow variances excluded
- Storage based on Lake Pillsbury 2016 bathymetric survey (water supply storage capacity is 76,876 ac-ft)
- Based on the model verification, the PVP model may exhibit some bias in accretions between Scott Dam and Cape Horn dam in the spring of some years due to downstream gage error- this translates into over/under estimate of flows below Van Arsdale (E-11) that is consistently applied to all scenarios
- Van Arsdale storage used to meet RPA flows

Baseline Conditions

- *Current Operations on the Russian River*
- *Current Operations on the Eel River*

- Buffers for minimum instream flows range from 5 cfs to 20 cfs below E-11 (Van Arsdale), depending on magnitude of the minimum instream flow. Flow buffer for meeting minimum instream flows on the East Fork Russian River at the E-16 PVP diversion are always 5 cfs. These flow buffers are for all scenarios where applicable.
- Calpella reach demands, which includes PVID demands, are approximately 8,600 acre-feet annually

Russian River:

- Flow source to Lake Mendocino = Unimpaired Flows + modeled PVP diversions – Calpella reach loss
- Historic unimpaired flows computed using USGS Basin Characterization Model.
- Storage based on Lake Mendocino 2001 bathymetric survey (water supply storage capacity is 111,000 ac-ft).
- Minimum flow releases to the East Branch Russian River below Potter Valley Powerhouse and below Lake Mendocino based on the 2008 Biological Opinion RPA and 1986 Decision 1610.
- Minimum flood control releases based on existing ACOE rule curve (no Forecast Information Reservoir Operations [FIRO]).
- Hydrologic index used for minimum flow releases based on 1986 Decision 1610 (inflow to Lake Pillsbury rather than Lake Mendocino)
- Assumptions for losses in the East Branch Russian River include 8,600 ac-ft loss from E-16 to Calpella and none from Calpella to Lake Mendocino
- Buffer for minimum instream flows below Lake Mendocino range from 5 cfs to 20 cfs, depending on the time of year and river reach, and are consistently used for all scenarios
- Hydrologic index used for minimum flow releases based on 1986 Decision 1610 (inflow to Lake Pillsbury)
- Assumed annual flow losses from Calpella to Lake Mendocino=8,600 ac-ft, losses below Lake Mendocino based on Fish Flow EIR based on depletion analysis for the period (clarification is in progress)

Differences between Model Assumptions for Baseline and Scenario 1

Eel River, same as Baseline, except:

- No Eel River storage
- No Block Water hydrographs released due to full PVP decommissioning
- Maximum Diversion Capacity = 0 cfs due to full PVP decommissioning (including Cape Horn Dam and Diversion)

Russian River, same as Baseline, except:

- No Eel River diversions to East Fork of the Russian River
- Potter Valley Irrigation District (PVID) demands met, to the extent possible, by local sources only (no pumpback from Lake Mendocino)

<p><u>Scenario 1:</u> <u>PVP Decommissioning</u></p> <ul style="list-style-type: none"> • <i>Current operations on the Russian River</i> • <i>Full decommissioning of Potter Valley Project, including all dams and diversions</i>

Example Hydrographs Comparing Flow Management Results

Example hydrographs have been provided for a recent dry year (Water Year [WY] 2015) and a recent dry year (WY 2017), as examples of how flows are predicted to change under Scenario 1, compared to baseline operations at Cape Horn Dam (E-11, Figure SC1-1 and Figure SC1-2), Lake Mendocino storage (Figure SC1-3 and Figure SC1-4), and the Russian River at Cloverdale (Figure SC1-5 and Figure SC1-6).

Cape Horn Dam (E-11). The Eel River hydrograph in a dry water year is similar to baseline, although flows are lower in October and in late spring, but slightly higher during the summer and early fall period (Figure SC1-1). Peak flow magnitudes are also higher than baseline conditions, as they would no longer be attenuated by storage in Lake Pillsbury. Under wetter conditions, flows are similar in the wet season, but unimpaired flows drop below baseline operations flows in the dry season (Figure SC1-2).

Lake Mendocino. During drier years, the model predicts that storage in Lake Mendocino is consistently lower than baseline operations storage. Lake Mendocino would be nearly depleted (<2,100 ac-ft) from approximately late summer through mid-winter (Figure SC1-3). During wetter years, storage would also be consistently lower than baseline, although Lake Mendocino would not be depleted (Figure SC1-4). During winter months, both Scenario 1 and baseline operations storage ultimately reach the Lake Mendocino rule curve (just under 70,000 AF), although this threshold is reached earlier in the water year under baseline operations.

Russian River at Cloverdale. During drier years spanning late summer through mid-winter, the model predicts similar flows under both baseline conditions and Scenario 1 (Figure SC1-5). However, under Scenario 1, flow is entirely depleted during dry periods due to Lake Mendocino storage depletion (only flows are from downstream tributary accretion). During a wetter water year, Scenario 1 flows remain very similar to baseline operations for most of the water year, although baseline operations winter and spring baseflows are slightly higher than Scenario 1 flows because of additional inflow coming from the tunnel diversion.

1 N/A because PVID pumpback does not occur.

2 Reported 2016 water use

3. OVERVIEW OF RESULTS

This summary of results compares Scenario 1 (PVP Decommissioning) to baseline operations, highlighting differences in flow and water storage availability at key locations in both the Eel River and Russian River basin.

Eel River Results (Below Scott Dam and Below Cape Horn Dam)

- Eel River flows become run-of-the river (can no longer be managed due to loss of storage in Lake Pillsbury). Flows would no longer be impounded behind Scott Dam during winter months and stored for release during drier parts of the year.
- Daily average flow in the reach below Lake Pillsbury would generally be 100 cfs to 200 cfs higher in winter and spring, and 100 cfs to 200 cfs lower during summer and early fall months without Scott Dam.
- Daily average flow in the reach below Cape Horn Dam are also 100 cfs to 200 cfs higher in winter and spring. During summer and fall, they are 10 cfs to 50 cfs lower, depending on the exceedance condition.
- In January and February, flows below Scott Dam are 10 cfs to 200 cfs higher during wetter conditions and up to approximately 100 cfs lower during drier conditions.
- During March and April, flows below Scott Dam are 10 cfs to 400 cfs higher than baseline operations.
- Beginning in May and continuing through December, flows below Scott Dam are 100 cfs to 150 cfs lower than baseline operations. The difference between the two scenarios is greatest during the June through October period, and is largely independent of water year conditions.
- Flows below Cape Horn Dam are up to 400 cfs higher than baseline operations from January through May, with the exact difference varying by water year condition.
- Flows remain as much as 75 cfs higher in June, as spring recession flows begin to transition into low summer baseflows.
- Beginning in July and continuing through October, flows below Cape Horn Dam are similar to baseline operations because baseline operations flows are similar to unimpaired flows during summer months.
- During November and December, flows are higher during wetter water year conditions and lower during drier water year conditions, compared to baseline operations.

Potter Valley Diversion Results

- There are no longer diversions from the Eel River to the East Fork Russian River, such that none of the PVID water demands are met by Eel River diversions.
- PVID operations would need to be altered to store local runoff and the existing canal system may have insufficient flow for distribution. Given limited local sources of water, there would likely be large deficits relative to current water demands.

Russian River Results

- Due to a lack of water supplementation from the PVP diversion, inflows to Calpella are as much as 270 cfs lower than baseline operations during the winter, spring, and late fall, and are 0 cfs (unimpaired) during summer and early fall months (June through October).

- Inflow to Lake Mendocino is also consistently lower (< 10 cfs to 50 cfs) than baseline operations during winter, spring, and early summer months, and there are no inflows to Lake Mendocino from as early as May through the beginning of November in many years, with exact dates dependent on exceedance condition.
- Storage in Lake Mendocino is consistently lower and would reach the minimum storage threshold (2,100 cfs) at an exceedance level of 40% and greater. Releases from Lake Mendocino would be limited to below 10 cfs after late summer during drier years (75% exceedance and higher), until precipitation returns in late fall.
- Along the Russian River downstream of Lake Mendocino (Forks, Hopland, Cloverdale, and Healdsburg), flows are slightly lower than baseline operations in January and February (< 10 cfs), nearly the same in March, April, and May, and again lower (approximately 40 cfs to 50 cfs) for the balance of the year (June-December). During drier water years (75% exceedance and higher), flows in the Russian River could decrease below 10 cfs in late summer through October.

APENDIX OF DETAILED RESULTS COMPARING
BASELINE OPERATIONS AND SCENARIO 1
